

# *Chapter 1*

---

# Basic Principles of Digital Systems

# *Analog vs. Digital*

---

## □ Analog:

- A way of representing a physical quantity by a proportional continuous voltage or current.

## □ Digital:

- A way of representing a physical quantity in discrete voltage steps.

# *Analog Electronics*

---

- ❑ Values are continuously variable between defined values.
- ❑ Can have any value within a defined range.

# *Analog Electronics*

---

# *Digital Electronics*

---

- ❑ Values can vary only by distinct(與其他不同的), or discrete(不連接的), steps.
- ❑ Can only have two values.

## *1.2 Digital Logic Levels*

---

- ❑ Logic HIGH is the higher voltage and represented by binary digit '1'.
- ❑ Logic LOW is the lower voltage and represented by binary digit '0'.

# *Digital Logic Levels*

---

## *1.3 Binary Number System*

---

- ❑ Uses two digits, 0 and 1.
- ❑ Represents any number by using the positional notation.

# *Positional Notation*

---

- ❑ The value of a digit depends on its placement within a number.
- ❑ In base 10, the positional values are (starting to the left of the decimal) –  
1 ( $10^0$ ), 10 ( $10^1$ ), 100 ( $10^2$ ), 1000 ( $10^3$ ), etc.
- ❑ In base 2, the positional values are  
1 ( $2^0$ ), 2 ( $2^1$ ), 4 ( $2^2$ ), 8 ( $2^3$ ), etc.

# *Decimal Equivalence of Binary Numbers*

---

$$\begin{aligned}1101 &= (1 \times 2^3) + (1 \times 2^2) + (0 \times 2^1) + (1 \times 2^0) \\&= (1 \times 8) + (1 \times 4) + (0 \times 2) + (1 \times 1) \\&= 8 + 4 + 0 + 1 \\&= 13\end{aligned}$$

# *Bit*

---

- ❑ Shorthand for binary digit, a logic 0 or 1.
- ❑ The most significant bit (MSB) is the leftmost bit of a binary number.
- ❑ The least significant bit (LSB) is the rightmost bit of a binary number.

# *Binary Inputs*

---

- ❑ Digital circuits operate by accepting logic levels (0,1) at their inputs.
- ❑ The corresponding outputs logic level will change (0,1).

# *Truth Table (真值表)*

---

- ☐ A list of output logic levels corresponding to all possible input combinations.
- ☐ The number of input combinations is  $2^n$ , where  $n$  is the number of inputs.
- ☐ A logic circuit with 3 inputs will have  $2^3$  or 8 possible input conditions.
- ☐ For this logic circuit there would also be 8 possible output conditions.

# *Constructing a Binary Sequence For a Truth Table – 1*

---

❑ Two methods:

- Learn to count in binary
- Follow a simple repetitive pattern

❑ Memorize the binary numbers from 0000 to 1111 and their decimal equivalents (0 to 15).

❑ Use the weighted values of binary bits.

# *Binary Sequence for a Truth Table – 1*

<i>Logic Level</i>			<i>Binary Value</i>			<i>Decimal Equivalent</i>
<i>A</i>	<i>B</i>	<i>C</i>	<i>A</i>	<i>B</i>	<i>C</i>	
L	L	L	0	0	0	0
L	L	H	0	0	1	1
L	H	L	0	1	0	2

H	L	L	1	0	0	4
H	L	H	1	0	1	5
H	H	L	1	1	0	6
H	H	H	1	1	1	7

## *Follow a Simple Repetitive Pattern*

---

- ❑ The LSB of any binary number alternates between 0 and 1 with every line.
- ❑ The next bit alternates every two lines.
- ❑ The next bit alternates every four lines, and so on.

## *Follow a Simple Repetitive Pattern (Cont'd)*

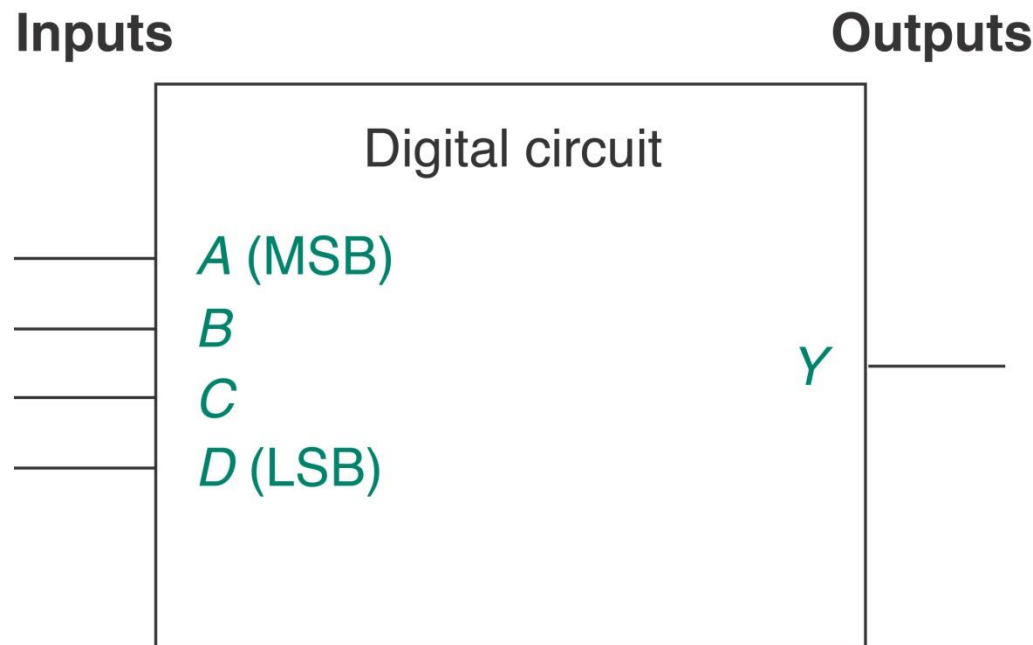

---

# *Decimal-to-Binary Conversion*

## (十進位-二進位轉換)

---

□ Two methods:

- Sum of powers(次方) of 2
- Repeated division by 2

# *Sum of Powers of 2*

---

## □ Step 1:

- Determine the largest power of 2 less than or equal to the number to be converted.
- Place a 1 in that positional location.

## □ Step 2:

- Subtract the number found in Step 1 from the number to be converted.
- For the new number, determine if the next lowest power of 2 is less than or equal to that number.

# *Sum of Powers of 2*

---

## □ Step 3:

- If the new power of two from Step 2 is larger, place a 0 in that positional location.
- If the new value is less than or equal, place a 1 in that positional location.

## □ Step 4:

- Repeat Steps 2 and 3 until there is nothing left to subtract.
- All remaining bits are set to 0.

# *Repeated Division by 2*

---

## □ Step 1:

- Take the number to be converted, and divide it by 2.
- The remainder(餘) (0 or 1) is the LSB of the binary value.

## □ Step 2:

- Divide the quotient (商) from Step 1 by 2.
- The remainder (0 or 1) is the next most significant bit.

## □ Step 3:

- Continue to execute Step 2 until the quotient is 0.
- The last remainder is the MSB.

# *Fractional (小數) Binary Numbers*

---

## □ Radix point (小數點):

- The generalized form of a **decimal point**(十進位小數點).  
The dividing line between positive and negative powers for positional multipliers.

## □ Binary point (二進位小數點):

- The radix point for binary numbers.

## *Fractional Binary Values*

---

- ❑ The value immediately to the right of the binary point is  $2^{-1} = 0.5$ .
- ❑ The next value to the right is  $2^{-2} = 0.25$ .
- ❑ The next value to the right is  $2^{-3} = 0.125$ , and so on.

# *Fractional Binary Weights*

---

$2^{-1}$	$2^{-2}$	$2^{-3}$	$2^{-4}$
$1/2$	$1/4$	$1/8$	$1/16$
0.5	0.25	0.125	0.0625

Each digit is multiplied by a positional factor that is a negative power of 2. The first four multipliers on either side of the binary point are:

				binary point				
$2^3$	$2^2$	$2^1$	$2^0$		$2^{-1}$	$2^{-2}$	$2^{-3}$	$2^{-4}$
= 8	= 4	= 2	= 1		= 1/2	= 1/4	= 1/8	= 1/16

## *Example 1.5: Binary Fraction*

---

Write the binary fraction 0.101 101 as a decimal fraction.

■ **Solution**

## ***Fractional-Decimal-to-Fractional-Binary Conversion*** (十進位小數轉二進位小數)

---

### □ Step 1:

- Multiply the decimal fraction by 2.
- The integer part, 0 or 1, is the first bit to the right of the binary point.

### □ Step 2:

- Discard the integer part from Step 1 and repeat Step 1 until the fraction repeats or terminates.

## ***Fractional-Decimal-to-Fractional-Binary Conversion*** (十進位小數轉二進位小數)

---

Example 1.6 Convert  $0.95_{10}$  to its binary equivalent

## *1.4 Hexadecimal Numbers*

---

- ❑ Base 16 number system.
- ❑ Primarily used as a shorthand form of binary numbers.
- ❑ Values range from 0 to F with the letters A to F used to represent the values 10 to 15 respectively.
- ❑ Positional multipliers are powers of 16:  
 $16^0 = 1$ ,  $16^1 = 16$ ,  $16^2 = 256$ , etc.

Example 1.9   Convert 7C6H to decimal.

## *Decimal-to-Hexadecimal Conversion*

(十進位轉十六進位)

---

□ Two methods:

- Sum of Weighted Hexadecimal Digits.
- Repeated division by 16.

# *Decimal-to-Hexadecimal Conversion*

---

## □ Sum of weighted hexadecimal digits.

Ex: Convert  $135_{10}$  to hexadecimal

➤  $16^2 \qquad 16^1$   
 $256_{10} > 135_{10} > 16_{10}$

$16^2$	$16^1$	$16^0$	
0	8		$135 - 8 * 16^1 = 135 - 128 = 7$
0	8	7	$7 - 7 = 0$

$$\therefore 135_{10} = 87_{16}$$

**□ Sum of weighted hexadecimal digits.**

Example 1.11: Convert  $175_{10}$  to hexadecimal

# *Decimal-to-Hexadecimal Conversion*

---

## **□ Repeated division by 16**

Example 1.12: Convert  $31581_{10}$  to hexadecimal

## *Conversion Between Hexadecimal and Binary*

### (十六進位和二進位之間轉換)

---

□ Each hexadecimal digit represents 4 binary bits.

*Example: Converting FD69H to Binary*

HEX	F	D	6	9
BIN	1111	1101	0110	1001
DEC	15	13	6	9

## *Conversion Between Hexadecimal and Binary* (十六進位和二進位之間轉換)

---

Example 1.13 Convert 7EF8H to its binary equivalent.

## *1.5 Periodic Digital Waveforms*

---

- ❑ A periodic digital waveform is a time-varying sequence of logic HIGHs and LOWs that repeat over some period of time.
- ❑ Period ( $T$ ) is the time required for the pattern to repeat.
- ❑ Frequency ( $f$ ) is the number of times per second a signal repeats and is the reciprocal of period.
- ❑  $f = 1/T$

# Waveform Definitions

---

- ❑ Time HIGH ( $t_h$ ) is the time a logic signal is in its HIGH state.
- ❑ Time LOW ( $t_l$ ) is the time a logic signal is in its LOW state.
- ❑ Duty cycle is the ratio of the time a logic signal is HIGH ( $t_h$ ) to the period ( $T$ ).

$$\text{Duty Cycle} = t_h/T$$

## *Example 1.14: Periodic Digital Waveforms*

Calculate the **time LOW**, **time HIGH**, **period**, **frequency**, and percent **duty cycle** for each of the periodic waveforms

Sol:

# *Aperiodic Digital Waveforms*

---

- ❑ An aperiodic digital waveform is a time-varying sequence of logic HIGHs and LOWs that does not repeat.

## *Example 1.15*

---

A digital circuit generates the following strings of 0s and 1s:

- a.** 0011111101101011010000110000
- b.** 0011001100110011001100110011
- c.** 0000000011111111000000001111
- d.** 1011101110111011101110111011

*Question:*

The time between two bits is always the same. Sketch the resulting digital waveform for each string of bits. Which waveforms are periodic and which are aperiodic?

*Answer: ?*

# *Pulse Waveforms*

---

- ❑ A pulse is a momentary (短暫的) variation of voltage from one logic level to the opposite level and back again.
- ❑ Amplitude is the voltage magnitude of a pulse.
- ❑ Edge is the part of a pulse representing the transition from one logic level to the other.

# *Pulse Waveform Characteristics*

---

- ❑ Rising edge is the transition from LOW to HIGH.
- ❑ Falling edge is the transition from HIGH to LOW.
- ❑ Leading edge is the earliest transition.
- ❑ Trailing edge is the latest transition.

# *Pulse Waveforms*

---

**a. Ideal pulse (instantaneous transitions)**

**b. Nonideal pulse (1)**

# *Pulse Waveform Characteristics*

---

**a. Positive-going pulse**

**b. Negative-going pulse**

# *Pulse Waveform Timing*

---

- ❑ Pulse width ( $t_w$ ) is the time from the 50% point of the leading edge to the 50% point of the trailing edge.
- ❑ Rise time is the time from 10% to 90% amplitude of the rising edge.
- ❑ Fall time is the time from 90% to 10% amplitude of the falling edge.

# *Pulse Waveform Timing*
